Lecture 15. Convergence in Distribution, Continuous Mapping Theorem, Delta Method 11/7/2011 Approximation using CTL (Review) The way we typically use the CLT result is to approximate the distribution of $p_n(X_n) = \cdot$ by that of a standard normal. Note that if $p_n(X_n) = \cdot$ is exactly a $N(0;1)$ random ariable, v then X

Convergence in distribution of a sequence of random variables. In the lecture entitled Sequences of random variables and their convergence we explained that different concepts of convergence are based on different ways of measuring the distance between two random variables (how "close to each other" two random variables are). The concept of convergence in distribution is based on the following ...

Lecture-15: Lp convergence of random variables 1 Lp convergence Definition 1.1 (Lp space). Consider a probability space (W,F,P) . For any $p > 1$, we say that a random variable $X \in L_p$, if $E|X|^p < \infty$, and we can define a norm $\|X\|_p = (E|X|^p)^{1/p}$. Theorem 1.2 (Minkowski's inequality).

Note that although we talk of a sequence of random variables converging in distribution, it is really the cdfs that converge, not the random variables. In this very fundamental way convergence in distribution is quite different from convergence in probability or convergence almost surely. Theorem 5.5.12

Chapter 15 Convergence of Feller Processes This chapter looks at the convergence of sequences of Feller processes to a limiting process. Section 15.1 lays some ground work concerning weak convergence of processes with cadlag sample paths. Section 15.2 states and proves the central theorem about the convergence of sequences of Feller processes.

In general, convergence will be to some limiting random variable. However, this random variable might be a constant, so it also makes sense to talk about convergence to a real number. There are several different modes of convergence. We begin with convergence in probability. Definition 7.1 The sequence $\{X_n\}$ converges in probability to $X \dots$

Lecture 32: Central limit theorem The central limit theorem explains why the normal distribution $f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ is prevalent. If we add independent random variables and normalize them so that the mean is zero and the standard deviation is 1, then the distribution of the sum converges to the normal distribution.

We haven't talked about convergence in distribution yet. Except it does not imply convergence in mean square, which is a thing that requires a variance. As Ferguson puts it in Section 5, the convergence in the CLT is not uniform in the underlying distribution in the sense that for any n , there are distributions satisfying the hypotheses of the CLT but for which the distribution of $\sqrt{n}(X_n - \mu)/\sigma$ approximates the standard normal distribution arbitrarily poorly. However,
